Abstract

A path coloring of a graph G is a vertex coloring of G such that each color class induces a disjoint union of paths. We present two efficient algorithms to construct a path coloring of a plane graph.

The first algorithm, based on a proof of Poh, is given a plane graph; it produces a path coloring of the given graph using three colors.

The second algorithm, based on similar proofs by Hartman and Škrekovski, performs a list-coloring generalization of the above. The algorithm is given a plane graph and an assignment of lists of three colors to each vertex; it produces a path coloring of the given graph in which each vertex receives a color from its list.

Implementations of both algorithms are available.

1 Introduction

All graphs will be finite, simple, and undirected. See West [9] for graph theoretic terms. A path coloring of a graph G is a vertex coloring (not necessarily proper) of G such that each color class induces a disjoint union of paths. A graph G is path k-colorable if G admits a path coloring using k colors.

Broere & Mynhardt conjectured [1, Conj. 16] that every planar graph is path 3-colorable. This was proven independently by Poh [7, Thm. 2] and by Goddard [5, Thm. 1].

Theorem 1.1 (Poh 1990, Goddard 1991). If G is a planar graph, then G is path 3-colorable. \square

It is easily shown that the "3" in Theorem 1.1 is best possible. In particular, Chartrand & Kronk [4, Section 3] gave an example of a planar graph whose vertex set cannot be partitioned into two subsets, each inducing a forest.

Hartman [6, Thm. 4.1] proved a list-coloring generalization of Theorem 1.1 (see also Chappell & Hartman [3, Thm. 2.1]). A graph G is $path \ k$ -choosable if, whenever each vertex of G is assigned a list of k colors, there exists a path coloring of G in which each vertex receives a color from its list.

Theorem 1.2 (Hartman 1997). If G is a planar graph, then G is path 3-choosable. \Box

Essentially the same technique was used by Škrekovski [8, Thm. 2.2b] to prove a result slightly weaker than Theorem 1.2.

We discuss two efficient path-coloring algorithms based on proofs of the above theorems. We distinguish between a *planar* graph—one that can be drawn in the plane without crossing edges—and a *plane* graph—a graph with a given embedding in the plane.

In Section 2 we outline our graph representations and the basis for our computations of time complexity.

Section 3 covers an algorithm based on Poh's proof of Theorem 1.1. The algorithm is given a plane graph; it produces a path coloring of the given graph using three colors.

Section 4 covers an algorithm based Hartman's proof of Theorem 1.2, along with the proof of Škrekovski mentioned above. The algorithm is given a plane graph and an assignment of a list of three colors to each vertex; it produces a path coloring of the given graph in which each vertex receives a color from its list.

Implementations of both algorithms are available; see Bross [2].

2 Graph Representations and Time Complexity

We will represent a graph via adjacency lists: a list, for each vertex v, of the neighbors of v. A vertex can be represented by an integer $0 \dots n-1$, where n is the order of the graph.

A plane graph will be specified via a rotation scheme: a circular ordering, for each vertex v, of the edges incident with v, in the order they appear around v in the plane embedding; this completely specifies the combinatorial embedding of the graph. Rotation schemes are convenient when we represent a graph using adjacency lists; we simply order the adjacency list for each vertex v in clockwise order around v; no additional data structures are required.

We will assume an integer RAM model of computation The input for each algorithm will be a connected planar graph with n vertices and m edges, represented via adjacency lists. The input size will be n, the number of vertices. Note that $\mathcal{O}(m) = \mathcal{O}(n)$.

In Section 4, given an edge uv, we will need an efficient operation to find v's entry in u's adjacency list from u's entry in v's list. An augmented adjacency list is an adjacency list such that for any edge uv, a reference to v's entry in u's list is stored in u's entry in v's list, and vice versa. Given an adjacency list representation of a graph, an augmented adjacency list representation may be constructed in $\mathcal{O}(m)$ time via the following algorithm.

Algorithm 2.1.

Input: An adjacency list representation Adj of a graph G

- **Step 1:** Construct an augmented adjacency list Adj' copy of Adj with the reference portion of each entry uninitialized.
- **Step 2:** For each vertex v construct an array $\operatorname{Wrk}[v]$ storing vertex-reference pairs. For each v from 0 to n-1 iterate through $\operatorname{Adj'}[v]$. For each neighbor u in $\operatorname{Adj'}[v]$ let $r_{v,u}$ be a reference to u's entry in $\operatorname{Adj'}[v]$ and append the pair $(v, r_{v,u})$ to $\operatorname{Wrk}[u]$.
- **Step 3:** For each v from n-1 to 0 iterate through $\operatorname{Wrk}[v]$. At the pair $(u, r_{u,v})$ in $\operatorname{Wrk}[v]$ note that the last element of $\operatorname{Wrk}[u]$ is $(v, r_{v,u})$. Look up and assign references for the edge uv in Adj'. Remove $(v, r_{v,u})$ from the back of $\operatorname{Wrk}[u]$.

After completing Step 2 in Algorithm 2.1 the array Wrk[v] contains a pair $(u, r_{u,v})$ for each neighbor of v, sorted in increasing order of by the neighbor u. At a given vertex v in Step 3 in Algorithm 2.1, for each edge $uw \in E(G)$ such that u < w and v < w, we shall have the initialized references for uw in Adj'[u] and Adj'[w] and removed the pair $(w, r_{w,u})$ from Wrk[u]. The next iteration of Step 3 will handle edges uv with v > u.

3 Path Coloring: the Poh Algorithm

We will first describe Poh's algorithm for path 3-coloring plane graphs. If C is a cycle in a plane graph G we will use Int(C) to denote the subgraph of G consisting of C and all interior vertices and edges.

Algorithm 3.1 (Poh 1990).

Input: A weakly triangulated plane graph G with outer face a cycle $C = v_1, v_2, \ldots, v_k$. Additionally, suppose C is 2-colored such that each color class induces a path, $P_1 = v_1, v_2, \ldots, v_l$ and $P_2 = v_{l+1}, v_{l+2}, \ldots, v_k$ respectively.

- **Step 1:** If G = C then G is already path 3-colored and we are done. Otherwise there are two cases to consider.
- Case 1.1: Suppose C is an induced cycle in G. Let $u, w \in V(G) V(C)$ such that uv_1v_k and wv_lv_{l+1} are faces; note that u and w are unique, but may not be distinct. Since C is induced and $G \neq C$, G C is connected. Let $P_3 = u_1u_2 \dots u_r$ be a shortest u, w-path in G C. Color each vertex of P_3 with the third color not used in the 2-coloring of C. Let $C_1 = v_1v_2 \dots v_lu_ru_{r-1} \dots u_1$ and $C_2 = u_1u_2 \dots u_rv_{l+1}v_{l+2} \dots v_k$.
- Case 1.2: Suppose C is not an induced cycle. Then there exists an edge $v_i v_j \in E(G) E(C)$ such that $i \leq l < j$. Let $C_1 = v_1 v_2 \dots v_i v_j v_{j+1} \dots v_k$ and $C_2 = v_i v_{i+1} \dots v_j$. Step 2: Apply Algorithm 3.1 to $Int(C_1)$ and $Int(C_2)$.
